**1** Complete the text using the words in the box.

physical connection · UDP · concept · TCP · lowest · Local Area Network · voice communication · medium · traffic · protocols

In order to make a network possible first of all you need a transport **1**. This can be a **2**, such as a copper wire or optic fibre, or it could be the air (WLAN). In order to get **3** flowing, you need protocols ruling how data is sent, received and interpreted by the networked devices.

The **4** are stacked in several layers and together they make up the Internet Protocol Suite. On the **5** layer (the Link Layer) there is a protocol dealing with digital electronics. In a LAN or **6**, this is the Ethernet Protocol. On top of this comes the Internet layer (yes, it is called that even in a LAN). Here we have – among others – the Internet Protocol. From this point on a **7**, referred to as IP addressing, becomes available. Next, in the Transport Layer, we find the Transmission Control Protocol or **8** for short, and User Datagram Protocol (**9**). Again, there may be other protocols in this layer. One more layer up is the Application Layer, which has protocols we know from everyday use, such as HTTP, SMTP and also protocols for P2P (peer to peer) **10**.
